

Notification Email Useage

The email service is coded in java and uses the external org.json package.

To send an email you need to create a json object. We implemented a function for you to do just that .

Create a json object by calling:

Email.createAndSendJsonObject(email: string, userName : string , msgType: string , subject : string)

where email = the email address to send an email to

userName = the user name who the address belongs to.

MsgType = determines the email template eg:

(conformation ,passwordChange)

conformation – sends email that account was successfully created

passwordChange – sends an email to user that allows them to change their password

this function will handle the creation and the sending of the email
